

Social Networks: A Fast Tour From People to Groups!

Matthew A. Hoover

02 May 2017

Welcome!

- Data scientist at Gallup
- Ph.D. in public policy
 - ▶ Dissertation on the effects of children's social networks on education in rural Afghanistan
 - ▶ Research on how social networks affected individual decision-making
- Previous life, 15+ years in international development along with additional work for a healthcare startup

What is social network analysis?

- Understanding the structure, composition, and purpose of people's social networks, whether in-person or online
- It helps answers questions from “how do my friends and acquaintances affect my behaviors” to “from whom can I seek support in a given situation”
- **Structure** identifies how ties connect people in certain ways – are there mutual ties, triangles, cycles?
- **Composition** describes the characteristics of people that are connected – are they the same gender, about the same age?
- **Purpose** of a particular network varies – is it a support network, drug seeking/using network, professional network?

Let's start small: The individual

- The individual plays the key role in most econometric analyses

Types of analysis (thank goodness for computers!)

- Early network analysis (circa 1920s) was done by hand on small networks (10-12 people)
- With computers, our reach is greatly expanded:
 - ▶ Descriptive statistics
 - ▶ Dyadic models
 - ▶ Exponential random graph models
 - ▶ Stochastic actor oriented models
- Underneath it all though, visualization of networks has been an important analysis tool since the beginning

Visualization – the problem

- The problem with network visualization is quite simple: there are programs that do good visualization (Gephi, Visone) and there are programs that do good statistical work (R), but there were really none that did both (Python is starting to change this)
- This posed a problem to me, as I had 62 networks I needed to visualize for my dissertation and I didn't want to use a lot of different programs to accomplish my tasks (data management, analysis, visualization)
- Since each network can be thought of as a square matrix of 1's and 0's, I opted to figure out a solution inside R or with a program that R could plug into
- Visone had an R plug-in, but due to changes in R with release 3.0, that no longer worked
- I was stuck with visualizations in R, which left me with this:

Visualization – the problem

(The start of) a solution

- I was unhappy with a number of things:
 - ▶ The color palette was jarring
 - ▶ The resolution and plotting area was quite limited
 - ▶ Controlling attributes (size/color of nodes) was difficult
 - ▶ Most importantly, I could not “set” node coordinates to replicate a different network with the same actors
- As I thought about solutions, I was using the `ggplot2` package in other work, so I thought I would try and create a `ggplot2`-like visualization for networks
- Let's look a bit more at the native and my `ggplot2`-inspired visualization

Native R plotting: `gplot`

- Uses R's base graphing features, layout, and language
- Limited color palette (8 colors), then it will recycle through colors
- Adding legends is difficult
- No way to capture/fix node coordinates
- However, very flexible in the format data can be fed to the function
- Let's look at it within R

gplot: Basic plot

gplot: Colored nodes

gplot: Colored and shaped nodes

gplot: With legend

Social Network – V02

Plotting with ggplot2: ggnet

- Utilizes ggplot2 for setup and graphing
- Code builds on component pieces of ggplot2, such as lines, points, axes, and legends
- Can specify coordinates for nodes or use random layout
- Legends auto-generated
- Variety of color palettes and objects types can be used for attributes
- Requires a specific data object class (`network` class)
- Let's have a look within R

ggnet: Basic plot

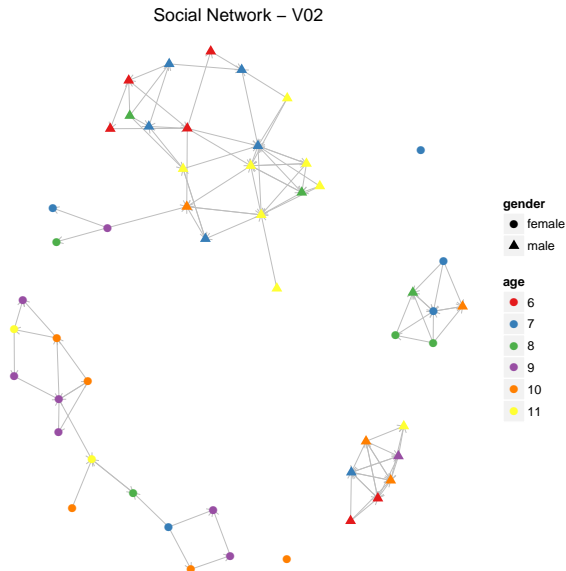

ggnet: Colored nodes

ggnet: Colored and shaped nodes

ggnet: With legend

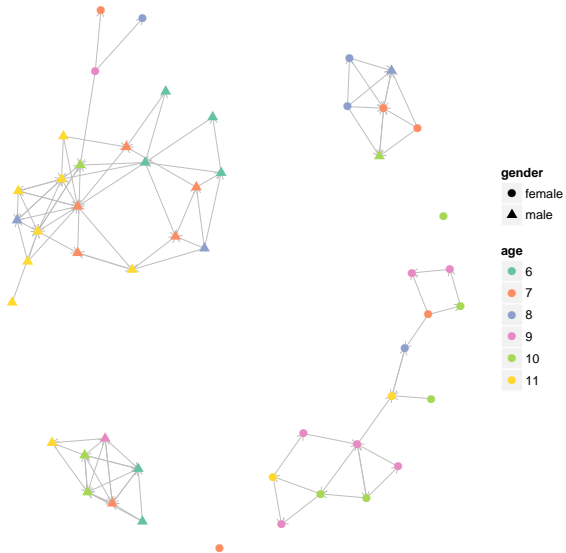

ggnet: Same network, different ties

ggnet: Same network, different ties, node placement set

ggnet: Different color palette

ggnet: Color gradient

Comparing and contrasting gplot and ggnet

- gplot has better flexibility for input; ggnet requires a specific data source
- ggnet has streamlined parameter entry
- gplot has a greater variety of attributes for nodes and edges
- ggnet has easier legend capabilities
- gplot can handle one- and two-mode networks; ggnet does not have the capability, currently
- ggnet allows for color gradient on continuous variables
- Both have extensive outputting capabilities for use outside of R

Summary

- Do it yourself! I had a need and while the solution isn't perfect, it was fun to put something together and keep working on it
- Next steps:
 - ▶ Build out the two-mode features of `ggnet`
 - ▶ Consolidate and create more efficient code
 - ▶ Create an R package for submission to CRAN
- Which function to use depends on need – `gplot` for initial visualizations, `ggnet` for final visualizations

Thank you!

- Thank you for your time!
